Energy stable discontinuous Galerkin formulations using discrete differential operators

Jesse Chan

Abstract

We show that, for non-linear hyperbolic conservation laws which admit a skew-symmetric splitting, energy stable discontinuous Galerkin (DG) methods can be constructed in a straightforward manner based on discrete DG gradient and divergence operators. In particular, we show that these formulations remain energy stable for both curvilinear geometries and inexact quadrature. Examples of energy stable formulations are given for variable advection, Burgers' equation, and a Burgers'-like system, and it is shown that the construction of DG methods based on discrete differential operators recover known entropy-conservative fluxes.

1 Introduction

[1]

Lifting operators and discrete gradients [2, 3]

2 Discrete differential operators

We assume that the domain Ω is decomposed into non-overlapping elements D^k. We define the mesh $\Omega_h = \cup D^k$ and the corresponding global approximation space $V_h(\Omega_h) = \bigoplus V_h\left(D^k\right)$, where $V_h\left(D^k\right)$ is the approximation space over a single patch. Furthermore, we introduce the jump and average of discontinuous functions across element interfaces. Let $D^{k,+}$ denote the neighboring element of across a face f of D^k, and let u^+, u^- denote the values of u on $D^{k,+}$ and D^k, respectively. The jump of u across f is then defined as

$$\llbracket u \rrbracket = u^+ - u^-, \qquad \{\{u\}\} = \frac{u^+ + u^-}{2}.$$

On faces which coincide with the boundary $\partial\Omega$, the average and jump are defined as

$$\llbracket u \rrbracket = 0, \qquad \{\{u\}\} = u.$$

The jump and average of vector fields are defined component-wise using the jumps and averages of components.

We will assume for now that all elements are affine mappings of a reference element $\widehat{D}$.

2.1 Discrete inner products

In order to define discrete differential operators, we first introduce the L^2 inner product on $V_h\left(\Omega_h\right)$

$$(u, v)_\Omega = \sum_{D^k} \int_{D^k} uv \, \mathrm{d}x = \sum_{D^k} \int_{\widehat{D}} uvJ \, \mathrm{d}\widehat{x},$$

and the associated L^2 projection $\Pi_N : L^2\left(\Omega\right) \to P^N$

$$(\Pi_N u, v)_\Omega = (u, v)_\Omega.$$

In practice, these integrals are computed using quadrature, such that

$$\int_{\widehat{D}} uv = \sum_{i=1}^{N_q} u(\boldsymbol{x}_i)v(\boldsymbol{x}_i)w_i, \tag{1}$$

where N_q is the number of quadrature points. The only assumptions we make upon this quadrature is that it is sufficiently accurate such that

1. The quadrature induces an L^2-equivalent inner product over the reference element $\widehat{D}$.

2. The quadrature is sufficiently accurate such that integration by parts holds with respect to the reference coordinates $\widehat{x}$.

2.2 Discrete derivatives

We introduce two discrete DG derivatives in this section. The first is the implicit definition used in [3]:

Definition 1. The discontinuous Galerkin differentiation operator $D^i : L^2(\Omega) \to V_h$ is defined implicitly as follows:

$$\left(D^i u, v\right)_{\Omega_h} = \sum_{D^k} \left(\left(-u, \frac{\partial v}{\partial \boldsymbol{x}_i}\right)_{L^2(D^k)} + \langle \{\!\{u\}\!\}, v\boldsymbol{n}_i \rangle_{L^2(\partial D^k)} \right), \qquad \forall v \in V_h.$$

We note that, for $u, v \in V_h$, (discrete) integration by parts yields an equivalent definition of D^i found in [4, 5]

$$\left(D^i u, v\right)_{\Omega_h} = \sum_{D^k} \left(\left(\frac{\partial u}{\partial \boldsymbol{x}_i}, v\right)_{L^2(D^k)} - \frac{1}{2} \langle [\![u]\!], v\boldsymbol{n}_i \rangle_{L^2(\partial D^k)} \right), \qquad \forall v \in V_h.$$

The main property of the discrete derivatives utilized in this work is a discrete integration-by-parts formula.

Lemma 1. Let $u, v \in V_h$. Then,

$$\left(D^i u, v\right) = \left(-u, D_h^i v\right) + \int_{\partial \Omega} uv\boldsymbol{n}_i$$

$$\left(D_h^i u, v\right) = \left(-u, D_h^i v\right) + \int_{\partial \Omega} uv\boldsymbol{n}_i.$$

Proof. Ez ☐

For $u \notin V_h$, due to the fact that the quadrature rule (1) may not be exact, and these two definitions are not equivalent and Lemma 1 does not hold. This motivates the definition of a *discrete* DG differentiation operator:

Definition 2. The discrete discontinuous Galerkin differentiation operator $D_h^i : L^2(\Omega) \to V_h$ is defined as $D_h^i = D^i \Pi_N$.

Using these discrete derivatives, we can define discrete gradient and divergence operators

Definition 3. Let $u \in V_h$ and $\boldsymbol{u} \in (V_h)^d$. Then, discrete gradient and divergence operators are defined as follows:

$$\left(\nabla^{\mathrm{DG}} u\right)_i = D^i u, \qquad \nabla^{\mathrm{DG}} \cdot \boldsymbol{u} = \sum_{i=1}^{d} D^i \boldsymbol{u}_i$$

$$\left(\nabla_h^{\mathrm{DG}} u\right)_i = D_h^i u, \qquad \nabla_h^{\mathrm{DG}} \cdot \boldsymbol{u} = \sum_{i=1}^{d} D_h^i \boldsymbol{u}_i.$$

2

2.3   Examples

- Tensor product elements: inner product computed using GLL nodes, Π_N reduces to nodal interpolation
- General elements: Π_N is just quadrature-based projection.
- General elements: Π_N can be taken to be nodal interpolation.

3   Notes

Begin with the gradient. Multiplication by $\boldsymbol{v}$ and integration by parts gives

$$\sum_{D^k} (\nabla u, \boldsymbol{v})_{L^2(D^k)} = \sum_{D^k} (-u, \nabla \cdot \boldsymbol{v})_{L^2(D^k)} + \langle u, \boldsymbol{v} \cdot \boldsymbol{n} \rangle_{L^2(\partial D^k)}.$$

We replace the values of u with $\{\{u\}\}$ on each element boundary to define the global DG gradient operator ∇_h

$$\sum_{D^k} (\nabla_h u, \boldsymbol{v})_{L^2(D^k)} := \sum_{D^k} (-u, \nabla \cdot \boldsymbol{v})_{L^2(D^k)} + \langle \{\{u\}\}, \boldsymbol{v} \cdot \boldsymbol{n} \rangle_{L^2(\partial D^k)}.$$

Integrating by parts again and the introduction of the lift operator shows that

$$\nabla_h u = \nabla u + \frac{1}{2} L \left([\![u]\!] \boldsymbol{n} \right)$$

where L is the lift operator.

The DG divergence operator is similarly defined as

$$\sum_{D^k} (\nabla_h \cdot \boldsymbol{u}, v)_{L^2(D^k)} := \sum_{D^k} (-\boldsymbol{u}, \nabla v)_{L^2(D^k)} + \langle \{\{\boldsymbol{u}\}\} \cdot \boldsymbol{n}, v \rangle_{L^2(\partial D^k)}.$$

and

$$\nabla_h \cdot u = \nabla \cdot u + \frac{1}{2} L \left([\![\boldsymbol{u}]\!] \cdot \boldsymbol{n} \right)$$

and it can be shown that

$$(\nabla_h u, \boldsymbol{v}) = (-u, \nabla_h \cdot \boldsymbol{v}).$$

We will incorporate boundary conditions in a stable way in the following sections.

When the support of v is limited to a single element, we have

$$(\nabla_h \cdot \boldsymbol{u}, v \mathbb{1}_{D^k}) = (\boldsymbol{u}, \nabla \cdot v \mathbb{1}_{D^k}) + \langle \{\{\boldsymbol{u}\}\} \cdot \boldsymbol{n}, v \rangle_{\partial D^k}.$$

and as a result when $v = 1$

$$(\nabla_h \cdot \boldsymbol{u}, \mathbb{1}_{D^k}) = \int_{\partial D^k} \{\{\boldsymbol{u}\}\} \cdot \boldsymbol{n}$$

3.1   Local conservation

Writing this in non-conservative form raises the question of local conservation. Integrating the original equation over D^k and using Gauss' theorem gives

$$\int_{D^k} \frac{\partial u}{\partial t} + \int_{\partial D^k} \beta_n u = 0.$$

Taking $v = 1$ on D^k yields

$$\int_{D^k} \frac{\partial u}{\partial t} + \frac{1}{2} \left(\nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u \right), \mathbb{1}_{D^k} \right) + \frac{1}{2} \left(\boldsymbol{\beta} \cdot \nabla_h u, \mathbb{1}_{D^k} \right) + \frac{1}{2} \left((\nabla \cdot \boldsymbol{\beta}) u, \mathbb{1}_{D^k} \right) = 0.$$

3

The first term gives

$$\left(\nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u\right), \mathbb{1}_{D^k}\right) = \int_{\partial D^k} \{\{\Pi_N \left(\boldsymbol{\beta} u\right)\}\} \cdot \boldsymbol{n}.$$

The second term gives

$$\left(\boldsymbol{\beta} \cdot \nabla_h u, \mathbb{1}_{D^k}\right) = \left(\nabla u, \boldsymbol{\beta}\right)_{D^k} + \frac{1}{2} \left\langle [\![u]\!], \boldsymbol{\beta} \cdot \boldsymbol{n}\right\rangle = \left(u, -\nabla \cdot \boldsymbol{\beta}\right)_{D^k} + \left\langle \{\{u\}\}, \boldsymbol{\beta} \cdot \boldsymbol{n}\right\rangle$$

through integration by parts and an assumption that $\boldsymbol{\beta} \cdot \boldsymbol{n}$ is periodic. Cancelling volume terms, we end up with the statement of local conservation

$$\int_{D^k} \frac{\partial u}{\partial t} + \frac{1}{2} \int_{\partial D^k} \left(\{\{\Pi_N \left(\boldsymbol{\beta} u\right)\}\} + \left(\Pi_N \left(\boldsymbol{\beta}\right) \{\{u\}\}\right)\right) \cdot \boldsymbol{n} = 0$$

which is a discrete version of the continuous statement of local conservation.

Penalization can be added by adding any positive-definite stabilization term (upwind, penalty, Lax-Friedrichs) through the regular divergence flux.

It's probably better to formulate this using continuous DG derivatives, recover flux terms, then discretize that - the flux terms *should* still cancel out after discretization, right?

4   Variable advection

A split formulation for advection is

$$\left(\frac{\partial u}{\partial t}, v\right) + \frac{1}{2} \left(\nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u\right), v\right) + \frac{1}{2} \left(\boldsymbol{\beta} \cdot \nabla_h u, v\right) + \frac{1}{2} \left(\left(\nabla \cdot \boldsymbol{\beta}\right) u, v\right) = 0.$$

Taking $v = u$ yields and using $\left(\nabla_h u, \boldsymbol{v}\right) = \left(-u, \nabla_h \cdot \boldsymbol{v}\right)$ yields the energy statement

$$\frac{1}{2} \|u\|^2 + \frac{1}{2} \left(\nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u\right), u\right) - \frac{1}{2} \left(u, \nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u\right)\right) = \frac{1}{2} \left(-\left(\nabla \cdot \boldsymbol{\beta}\right) u, u\right),$$

implying that $\frac{1}{2} \|u\|^2 = 0$ if $\nabla \cdot \boldsymbol{\beta} = 0$, or that the method is energy conserving. The only difference in this formulation is the introduction of Π_N, which can be defined at a discrete level using any quadrature scheme for which a discrete projection is well-defined.

5   Discrete DG derivatives

Methods based on discrete DG derivatives also work.

The discrete DG derivative-based method is not consistent in the sense that Galerkin orthogonality does not hold exactly. The difference lies in the flux terms. Assume $\nabla \cdot \boldsymbol{\beta} = 0$, then

$$\left(\frac{\partial u}{\partial t}, v\right) + \frac{1}{2} \left(-\boldsymbol{\beta} u, \nabla_h v\right) + \frac{1}{2} \left(\boldsymbol{\beta} \cdot \nabla_h u, v\right) = 0.$$

$$\left(\nabla_h \cdot \Pi_N \left(\boldsymbol{\beta} u\right), v\right) = \sum_{D^k} \left(-\boldsymbol{\beta} u, \nabla v\right)_{L^2(D^k)} + \left\langle \{\{\Pi_N \left(\boldsymbol{\beta} u\right)\}\} \cdot \boldsymbol{n}, v\right\rangle_{L^2(\partial D^k)}$$

$$\left(\nabla_h u, \boldsymbol{\beta} v\right) = \sum_{D^k} \left(-u, \nabla \cdot \left(\boldsymbol{\beta} v\right)\right)_{L^2(D^k)} + \left\langle \boldsymbol{\beta} \cdot \boldsymbol{n} \{\{u\}\}, v\right\rangle_{L^2(\partial D^k)}.$$

The latter term is consistent; the former is not due to the presence of $\{\{\Pi_N \left(\boldsymbol{\beta} u\right)\}\} \cdot \boldsymbol{n}$ in the flux term. The consistency error should then be $O(h^{N+1/2})$ using a trace inequality for L^2 projections.

Note: can also use interpolants in a stable manner if using D_h. Unlike SEM, this still requires an extra matvec per RHS evaluation because of the lack of diagonality of the mass matrix. Reduces number of steps by one (no interpolation to quadrature points) but does not reduce number of total matvecs.

6 Curvilinear coordinates

For curvilinear meshes, J and $\boldsymbol{G}$ are no longer constant over each element. However, for isoparametric mappings (and special polynomial interpolations of general curvilinear mappings), metric identities hold [6] such that $\widehat{\nabla} \cdot (J\boldsymbol{G}) = 0$.

$$(\nabla u, \boldsymbol{v})_{D^k} = \left(J\boldsymbol{G}\widehat{\nabla}u, \boldsymbol{v} \right)_{\widehat{D}} = \left(-u, \widehat{\nabla} \cdot (J\boldsymbol{G}\boldsymbol{v}) \right) + \langle J\boldsymbol{G}\widehat{\boldsymbol{n}}u, \boldsymbol{v} \rangle$$

Noting that $J\boldsymbol{G}\widehat{\boldsymbol{n}} = \boldsymbol{n}J^f$ [7], we recover integration by parts over the physical element.

7 Extension to other hyperbolic problems

Example: acoustic wave equation, simply discretize by replacing $\nabla, \nabla\cdot$ with discrete versions. Automatically skew symmetric and energy stable via integration by parts. Also, can show why WADG works: discretize based on discrete divergence, then test with $T_{c^2}^{-1}p$ and use identities. Note - I think this requires the use of the strictly discrete version.

Example: Burgers' equation

Example: Kinetic energy preserving splitting of Euler (assumes exact time discretization). Doesn't seem to help much without extra viscosity?

Example: Entropy splitting of Buckley-Leverett?

Example: Entropy splitting of Euler (note - cannot extend to Navier-Stokes in an entropy-stable fashion due to fact that heat flux matrix is not symmetrizable w.r.t. homogeneous flux function, though viscous terms are. This impacts only boundary conditions.)
